UK

# Learning Outcome

- ❖ To learn to represent vectors
- ❖ To know how to perform basic operations like addition, scalar multiplication, projection using vectors
- ❖ To understand how to perform dot product and cross product of vectors

# Outline

3

- ❖ Introduction and Motivation of Vectors
- ❖ Vector Operations
  - ❖ Addition
  - ❖ Scalar multiplication
  - ❖ Linear Combination
- ❖ Component Representation
  - ❖ Vector Length
  - ❖ Vector Algebra
- ❖ Unit Vector
- ❖ Dot product of Vectors
- ❖ Projection
  - ❖ Scalar
  - ❖ Vector
- ❖ Cross-Product of Vectors

# Motivation

# Uses of Vectors in Data Science

- ❖ Vectors are important for many different areas of **machine learning** and pattern processing
- ❖ In **machine learning**, feature **vectors** are **used** to represent numeric or symbolic characteristics, called features, of an object in a mathematical, easily analyzable way.

# Uses of Vectors in Data Science

- ❖ There are many quantities which require only 1 measurement to describe them. e.g Length of a string, or area of any shape or temperature of any surface (Such quantities are called *scalars* )
- ❖ However, most of the quantities or datasets require at **least 2 measurements** to describe them. Along with the magnitude, they have a “direction” associated e.g velocity or force. Hence, they need vector representation.

# Example

- ❖ Let's say you are collecting some data about a group of students in a class. You are measuring the height and weight of each student and the data collected for 5 students is as follows:

Heigt (in feets)	Weight (in Kgs)
6	80
5.4	54
5	50
5.7	65
5.8	72

- ❖ Each individual measurement here is a scalar quantity. So height or weight viewed stand-alone are scalars.
- ❖ However, when you look at the observation about each student as a whole i.e height and weight together for every student, you can think of it as a **vector**.

# Example

- ❖ Hence, we can represent the data all the 5 students using vectors.
- ❖ Similarly, machine learning algorithms **use vectors representation to process high dimensional data**

# Introduction to Vectors

# Vectors

- ❖ The term vector is used by scientists to indicate a quantity (such as displacement or velocity or force) that has both **magnitude and direction**.
- ❖ A vector is often represented by an **arrow or a directed line segment**. The length of the arrow represents the **magnitude** of the vector and the **arrow points in the direction of the vector**.
- ❖ We denote a vector by printing a letter in boldface ( $\mathbf{v}$ ) or by putting an arrow above the letter  $(\overrightarrow{v})$

# Vectors

- ❖ For instance, suppose a particle moves along a line segment from point A to point B.
- ❖ The corresponding displacement vector  $\mathbf{v}$ , shown in Figure 1, has initial point A (the tail) and terminal point B (the tip) and we indicate this by writing

$$\mathbf{v} = \overrightarrow{AB}$$

# Equivalent Vectors

- ❖ Notice that the vector  $\mathbf{u}$  has the same length and the same direction as  $\mathbf{v}$  even though it is in a different position.
- ❖ We say that  $\mathbf{u}$  and  $\mathbf{v}$  are **equivalent (or equal)** and we write  $\mathbf{u} = \mathbf{v}$ .

$$\mathbf{u} = \overrightarrow{CD}$$

$$\mathbf{v} = \overrightarrow{AB}$$

**Figure 1**  
Equivalent vectors

# Zero Vectors

- ❖ The zero vector, denoted by  $\mathbf{0}$ , has length 0. It is the only vector with no specific direction.

# Combining/ Adding Vectors

# Combining Vectors

15

- ❖ Suppose a particle moves from A to B, so its displacement vector is  $\vec{AB}$ .
- ❖ Then the particle changes direction and moves from B to C, with displacement vector  $\vec{BC}$  as in Figure 2.
- ❖ The combined effect of these displacements is that the particle has moved from A to C.
- ❖ The resulting displacement vector  $\vec{AC}$  is called the **sum of**  $\vec{AB}$  and  $\vec{BC}$ , we write

$$\vec{AC} = \vec{AB} + \vec{BC}$$

Figure 2

# Combining Vectors

**Definition of Vector Addition** If  $\mathbf{u}$  and  $\mathbf{v}$  are vectors positioned so the initial point of  $\mathbf{v}$  is at the terminal point of  $\mathbf{u}$ , then the **sum**  $\mathbf{u} + \mathbf{v}$  is the vector from the initial point of  $\mathbf{u}$  to the terminal point of  $\mathbf{v}$ .

❖ The definition of vector addition is illustrated in Figure 3. You can see why this definition is sometimes called the **Triangle Law**.

Figure 3

The Triangle Law

# Combining Vectors

❖ In Figure 4 we start with the same vectors  $u$  and  $v$  as in Figure 3 and draw another copy of  $v$  with the same initial point as  $u$ .

Figure 4

The Parallelogram Law

❖ Completing the **parallelogram**, we see that  $u + v = v + u$ .

❖ **Parallelogram Law** : If we place  $u$  and  $v$  so they start at the same point, then  $u + v$  lies along the **diagonal** of the parallelogram with  $u$  and  $v$  as sides. (This is called the **Parallelogram Law**.)

# Scalar Multiplication

# Scalar Multiplication

- ❖ It is possible to multiply a vector by a **real number  $c$** . (In this context we call the real number  $c$  a scalar to distinguish it from a vector.)
- ❖ For instance, we want  $2\mathbf{v}$  to be the same vector as  $\mathbf{v} + \mathbf{v}$ , which has the **same direction** as  $\mathbf{v}$  but is **twice** as long. In general, we multiply a vector by a scalar as follows.

**Definition of Scalar Multiplication** If  $c$  is a scalar and  $\mathbf{v}$  is a vector, then the **scalar multiple**  $c\mathbf{v}$  is the vector whose length is  $|c|$  times the length of  $\mathbf{v}$  and whose direction is the same as  $\mathbf{v}$  if  $c > 0$  and is opposite to  $\mathbf{v}$  if  $c < 0$ . If  $c = 0$  or  $\mathbf{v} = \mathbf{0}$ , then  $c\mathbf{v} = \mathbf{0}$ .

# Scalar Multiplication

❖ This definition is illustrated in Figure 7.

**Figure 7**  
Scalar multiples of  $\mathbf{v}$

# Scalar Multiplication

- ❖ Notice that two nonzero vectors are parallel if they are scalar multiples of one another.
- ❖ In particular, the vector  $-v = (-1)v$  has the **same length as  $v$  but points in the opposite direction**. We call it the negative of  $v$ .
- ❖ By the difference  $u - v$  of two vectors we mean
- ❖ 
$$u - v = u + (-v)$$

# Subtraction of Vectors

- ❖ So we can construct  $u - v$  by first drawing the negative of  $v$ ,  $-v$ , and then adding it to  $u$  by the Parallelogram Law as in Figure 8(a).
- ❖ Alternatively, since  $v + (u - v) = u$ , the vector  $u - v$ , when added to  $v$ , gives  $u$ . So we could construct  $u - v$  as in Figure 8(b) by means of the Triangle Law.

Figure 8(a)

Figure 8(b)

Drawing  $u - v$

# Vector Representation

# Vector Representation: Components

- ❖ For some purposes it's best to introduce a coordinate system and treat vectors algebraically.
- ❖ If we place **the initial point of a vector  $\mathbf{a}$  at the origin of a rectangular coordinate system**, then the terminal point of  $\mathbf{a}$  has **coordinates** of the form  $(a_1, a_2)$  or  $(a_1, a_2, a_3)$ , depending on whether our coordinate system is two- or three-dimensional (see Figure 11).

❖ These coordinates are called the **components** of  $\mathbf{a}$  and we write  $\mathbf{a} = \langle a_1, a_2 \rangle$  or  $\mathbf{a} = \langle a_1, a_2, a_3 \rangle$

$$\mathbf{a} = \langle a_1, a_2 \rangle$$

$$\mathbf{a} = \langle a_1, a_2, a_3 \rangle$$

Figure 11

# Position Vector

25

❖ In three dimensions, the vector  $\mathbf{a} = \overrightarrow{OP} = \langle a_1, a_2, a_3 \rangle$  is the **position vector** of the point  $P(a_1, a_2, a_3)$ . (See Figure 13.)

Representations of  $\mathbf{a} = \langle a_1, a_2, a_3 \rangle$

Figure 13

# Length or Magnitude of Vector

- ❖ The **magnitude or length** of the vector  $\mathbf{v}$  is denoted by the symbol  $|\mathbf{v}|$  or  $\|\mathbf{v}\|$ .
- ❖ By using the distance formula to compute the length of a segment OP (a vector through origin), we obtain the following formulas.

The length of the two-dimensional vector  $\mathbf{a} = \langle a_1, a_2 \rangle$  is

$$|\mathbf{a}| = \sqrt{a_1^2 + a_2^2}$$

The length of the three-dimensional vector  $\mathbf{a} = \langle a_1, a_2, a_3 \rangle$  is

$$|\mathbf{a}| = \sqrt{a_1^2 + a_2^2 + a_3^2}$$

# Vector Addition (Algebra)

- ❖ How do we add vectors algebraically?
- ❖ Figure 14 shows that if  $\mathbf{a} = \langle a_1, a_2 \rangle$  and  $\mathbf{b} = \langle b_1, b_2 \rangle$ ,
- ❖ The sum is  $\mathbf{a} + \mathbf{b} = \langle a_1 + b_1, a_2 + b_2 \rangle$ ,
- ❖ ( for the case where the components are **positive**).
- ❖ In other words, to **add** algebraic vectors we add their components. Similarly, to **subtract** vectors we subtract components.

Figure 14

# Scalar Multiplication (Algebra)

- ❖ To multiply a vector by a scalar we **multiply each component by that scalar**.
- ❖ From the similar triangles in Figure 15 we see that the components of  $ca$  are  $ca_1$  and  $ca_2$ .

Figure 15

# Linear Combination

For one vector  $u$ , the only linear combinations are the multiples  $cu$ . For two vectors, the combinations are  $cu + dv$ . For three vectors, the combinations are  $cu + dv + ew$ .

## ❖ Important Questions

- ❖ What is the picture of all combination of  $cu$ ?
- ❖ What is the picture of all combination of  $cu + dv$ ?

# Linear Combination

30

## ❖ Important Questions

- ❖ What is the picture of all combination of  $c\mathbf{u}$ ? Fill a line through  $(0,0)$
- ❖ What is the picture of all combination of  $c\mathbf{u} + d\mathbf{v}$ : **Fill a plane through  $(0,0)$**

# Properties of Vector

❖ Addition and scalar multiplication are defined in terms of components just as for the cases  $n = 2$  and  $n = 3$ .

**Properties of Vectors** If  $\mathbf{a}$ ,  $\mathbf{b}$ , and  $\mathbf{c}$  are vectors in  $V_n$  and  $c$  and  $d$  are scalars, then

1.  $\mathbf{a} + \mathbf{b} = \mathbf{b} + \mathbf{a}$

2.  $\mathbf{a} + (\mathbf{b} + \mathbf{c}) = (\mathbf{a} + \mathbf{b}) + \mathbf{c}$

3.  $\mathbf{a} + \mathbf{0} = \mathbf{a}$

4.  $\mathbf{a} + (-\mathbf{a}) = \mathbf{0}$

5.  $c(\mathbf{a} + \mathbf{b}) = c\mathbf{a} + c\mathbf{b}$

6.  $(c + d)\mathbf{a} = c\mathbf{a} + d\mathbf{a}$

7.  $(cd)\mathbf{a} = c(d\mathbf{a})$

8.  $1\mathbf{a} = \mathbf{a}$

# The standard basis vectors

❖ Three vectors in  $V_3$  play a special role. Let

$$\mathbf{i} = \langle 1, 0, 0 \rangle \quad \mathbf{j} = \langle 0, 1, 0 \rangle \quad \mathbf{k} = \langle 0, 0, 1 \rangle$$

❖ These vectors  $\mathbf{i}$ ,  $\mathbf{j}$ , and  $\mathbf{k}$  are called the **standard basis vectors**. They have length 1 and point in the directions of the positive  $x$ -,  $y$ -, and  $z$ -axes. Similarly, in two dimensions we define  $\mathbf{i} = \langle 1, 0 \rangle$  and  $\mathbf{j} = \langle 0, 1 \rangle$ . (See Figure 17.)

(a)

(b)

**Figure 17**

Standard basis vectors in  $V_2$  and  $V_3$

# The standard basis vectors

❖ If  $a = \langle a_1, a_2, a_3 \rangle$ , then we can write

$$\text{❖} \quad a = \langle a_1, a_2, a_3 \rangle = \langle a_1, 0, 0 \rangle + \langle 0, a_2, 0 \rangle + \langle 0, 0, a_3 \rangle$$

$$\text{❖} \quad = a_1 \langle 1, 0, 0 \rangle + a_2 \langle 0, 1, 0 \rangle + a_3 \langle 0, 0, 1 \rangle$$

$$\text{❖} \quad a = a_1 i + a_2 j + a_3 k$$

❖ Thus any vector in  $V_3$  can be expressed in terms of  $i$ ,  $j$ , and  $k$ . For instance,

$$\text{❖} \quad \langle 1, -2, 6 \rangle = i - 2j + 6k$$

❖ Similarly, in two dimensions, we can write

$$\text{❖} \quad a = \langle a_1, a_2 \rangle = a_1 i + a_2 j$$

# Unit Vector

❖ A unit vector is a vector whose length is 1.

❖ For instance,  $\mathbf{i}$ ,  $\mathbf{j}$ , and  $\mathbf{k}$  are all unit vectors. In general, if  $\mathbf{a} \neq \mathbf{0}$ , then the unit vector that has the same direction as  $\mathbf{a}$  is

$$\mathbf{u} = \frac{1}{|\mathbf{a}|} \mathbf{a} = \frac{\mathbf{a}}{|\mathbf{a}|}$$

❖ In order to verify this, we let  $c = 1/|\mathbf{a}|$ . Then  $\mathbf{u} = c\mathbf{a}$  and  $c$  is a positive scalar, so  **$\mathbf{u}$  has the same direction as  $\mathbf{a}$ .**

❖ Example:  $\mathbf{q} = \langle -2, 1 \rangle$ ,

❖ Magnitude:  $|\mathbf{q}| = \sqrt{(-2)^2 + 1^2} = \sqrt{5}$

Unit Vector:

$$\mathbf{u} = \frac{\langle -2, 1 \rangle}{\sqrt{5}} = \left\langle -\frac{2}{\sqrt{5}}, \frac{1}{\sqrt{5}} \right\rangle$$

# Dot Product

# The Dot Product

- ❖ So far we have added two vectors and multiplied a vector by a scalar. The question arises: **Is it possible to multiply two vectors so that their product** is a useful quantity? One such product is the dot product, whose definition follows.

**1 Definition** If  $\mathbf{a} = \langle a_1, a_2, a_3 \rangle$  and  $\mathbf{b} = \langle b_1, b_2, b_3 \rangle$ , then the **dot product** of  $\mathbf{a}$  and  $\mathbf{b}$  is the number  $\mathbf{a} \cdot \mathbf{b}$  given by

$$\mathbf{a} \cdot \mathbf{b} = a_1b_1 + a_2b_2 + a_3b_3$$

- ❖ Thus, to find the dot product of  $\mathbf{a}$  and  $\mathbf{b}$ , we multiply corresponding components and add.

# The Dot Product

- ❖ The **result is not a vector**. It is a real number, that is, a **scalar**. For this reason, the dot product is sometimes called the **scalar product** (or **inner product**).
- ❖ Although Definition 1 is given for three-dimensional vectors, the dot product of n-dimensional vectors is defined in a similar fashion:
- ❖ Example n=2:
- ❖  $\langle a_1, a_2 \rangle \cdot \langle b_1, b_2 \rangle = a_1 * b_1 + a_2 * b_2$

# The Dot Product

## Examples:

$$\diamond \langle 2, 4 \rangle \cdot \langle 3, -1 \rangle = 2(3) + 4(-1) = 2$$

$$\diamond \langle -1, 7, 4 \rangle \cdot \langle 6, 2, -\frac{1}{2} \rangle = (-1)(6) + 7(2) + 4(-\frac{1}{2}) = 6$$

$$\diamond (i + 2j - 3k) \cdot (2j - k) = 1(0) + 2(2) + (-3)(-1) = 7$$

# Properties of the Dot Product

❖ The dot product obeys many of the laws that hold for ordinary products of real numbers. These are stated in the following theorem.

**2 Properties of the Dot Product** If  $\mathbf{a}$ ,  $\mathbf{b}$ , and  $\mathbf{c}$  are vectors in  $V_3$  and  $c$  is a scalar, then

1.  $\mathbf{a} \cdot \mathbf{a} = |\mathbf{a}|^2$

2.  $\mathbf{a} \cdot \mathbf{b} = \mathbf{b} \cdot \mathbf{a}$

3.  $\mathbf{a} \cdot (\mathbf{b} + \mathbf{c}) = \mathbf{a} \cdot \mathbf{b} + \mathbf{a} \cdot \mathbf{c}$

4.  $(c\mathbf{a}) \cdot \mathbf{b} = c(\mathbf{a} \cdot \mathbf{b}) = \mathbf{a} \cdot (c\mathbf{b})$

5.  $\mathbf{0} \cdot \mathbf{a} = 0$

# The Dot Product

❖ These properties are easily proved using Definition 1. For instance, here are the proofs of Properties 1 and 3:

$$1. \mathbf{a} \cdot \mathbf{a} = a_1^2 + a_2^2 + a_3^2 = |\mathbf{a}|^2$$

$$❖ 3. \mathbf{a} \cdot (\mathbf{b} + \mathbf{c}) = \langle a_1, a_2, a_3 \rangle \cdot \langle b_1 + c_1, b_2 + c_2, b_3 + c_3 \rangle$$

$$❖ \quad = a_1(b_1 + c_1) + a_2(b_2 + c_2) + a_3(b_3 + c_3)$$

$$❖ \quad = a_1b_1 + a_1c_1 + a_2b_2 + a_2c_2 + a_3b_3 + a_3c_3$$

$$❖ \quad = (a_1b_1 + a_2b_2 + a_3b_3) + (a_1c_1 + a_2c_2 + a_3c_3)$$

$$❖ \quad = \mathbf{a} \cdot \mathbf{b} + \mathbf{a} \cdot \mathbf{c}$$

# Geometric Interpretation of the Dot Product

- ❖ The dot product  $\mathbf{a} \cdot \mathbf{b}$  can be given a geometric interpretation **in terms of the angle  $\theta$**  between  $\mathbf{a}$  and  $\mathbf{b}$ , which is defined to be the angle between the representations of  $\mathbf{a}$  and  $\mathbf{b}$  that start at the origin, where  $0 \leq \theta \leq \pi$ .

In other words,  $\theta$  is the angle between the line segments  $\overrightarrow{OA}$  and  $\overrightarrow{OB}$  in Figure 1.

- ❖ Note that if  $\mathbf{a}$  and  $\mathbf{b}$  are **parallel** vectors, then  $\theta = 0$  or  $\theta = \pi$ .

Figure 1

# Geometric Interpretation of the Dot Product

❖ The formula in the following theorem is used by physicists as the definition of the dot product.

**3 Theorem** If  $\theta$  is the angle between the vectors  $\mathbf{a}$  and  $\mathbf{b}$ , then

$$\mathbf{a} \cdot \mathbf{b} = |\mathbf{a}| |\mathbf{b}| \cos \theta$$

# Geometric Interpretation of the Dot Product

❖ **Example:** If the vectors  $a$  and  $b$  have lengths 4 and 6, and the angle between them is  $\pi/3$ , find  $a \cdot b$ ?

❖ **Solution:** Using Theorem 3, we have

$$\begin{aligned} \text{❖} \quad & a \cdot b = |a| |b| \cos(\pi/3) \end{aligned}$$

$$\begin{aligned} \text{❖} \quad & \\ \text{❖} \quad & = 4 \cdot 6 \cdot \frac{1}{2} \end{aligned}$$

$$\begin{aligned} \text{❖} \quad & \\ \text{❖} \quad & = 12 \end{aligned}$$

# Angle between two Vectors

❖ The formula in Theorem 3 also enables us to find the angle between two vectors.

**6 Corollary** If  $\theta$  is the angle between the nonzero vectors  $\mathbf{a}$  and  $\mathbf{b}$ , then

$$\cos \theta = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}| |\mathbf{b}|}$$

❖ Note:

**3 Theorem** If  $\theta$  is the angle between the vectors  $\mathbf{a}$  and  $\mathbf{b}$ , then

$$\mathbf{a} \cdot \mathbf{b} = |\mathbf{a}| |\mathbf{b}| \cos \theta$$

# Example 3

45

❖ Find the **angle** between the vectors  $\mathbf{a} = \langle 2, 2, -1 \rangle$  and  $\mathbf{b} = \langle 5, -3, 2 \rangle$ .

# Example 3

❖ Find the **angle** between the vectors  $\mathbf{a} = \langle 2, 2, -1 \rangle$  and  $\mathbf{b} = \langle 5, -3, 2 \rangle$ .

❖ **Solution:**

❖ Since,  $|\mathbf{a}| = \sqrt{2^2 + 2^2 + (-1)^2} = 3$  and  $|\mathbf{b}| = \sqrt{5^2 + (-3)^2 + 2^2} = \sqrt{38}$

❖  $\mathbf{a} \cdot \mathbf{b} = 2(5) + 2(-3) + (-1)(2) = 2$

$$\cos \theta = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}| |\mathbf{b}|} = \frac{2}{3\sqrt{38}}$$

❖

❖ So the angle between  $\mathbf{a}$  and  $\mathbf{b}$  is  $\theta = \cos^{-1}\left(\frac{2}{3\sqrt{38}}\right) \approx 1.46$  (or  $84^\circ$ )

# The Dot Product of Orthogonal or Perpendicular Vectors

- ❖ Two nonzero vectors  $\mathbf{a}$  and  $\mathbf{b}$  are called perpendicular or orthogonal if the angle between them is  $\theta = \pi / 2$ . Then Theorem 3 gives
- ❖  $\mathbf{a} \cdot \mathbf{b} = |\mathbf{a}| |\mathbf{b}| \cos(\pi / 2) = 0$
- ❖ and conversely if  $\mathbf{a} \cdot \mathbf{b} = 0$ , then  $\cos \theta = 0$ , so  $\theta = \pi / 2$ .
- ❖ The zero vector  $\mathbf{0}$  is considered to be perpendicular to all vectors.
- ❖ Therefore we have the **following method for determining whether two vectors are orthogonal.**

**7**

Two vectors  $\mathbf{a}$  and  $\mathbf{b}$  are orthogonal if and only if  $\mathbf{a} \cdot \mathbf{b} = 0$ .

# The Dot Product of Orthogonal or Perpendicular Vectors

❖ **Example :** Show that  $2\mathbf{i} + 2\mathbf{j} - \mathbf{k}$  is perpendicular to  $5\mathbf{i} - 4\mathbf{j} + 2\mathbf{k}$ ?

❖ **Solution:**

$$\text{❖ } (2\mathbf{i} + 2\mathbf{j} - \mathbf{k}) \cdot (5\mathbf{i} - 4\mathbf{j} + 2\mathbf{k}) = 2(5) + 2(-4) + (-1)(2) = 0$$

❖ these vectors are perpendicular.

# The Dot Product as a Measure of Direction of Two Vectors

- ❖ Because  $\cos \theta > 0$  if  $0 \leq \theta < \pi/2$  and  $\cos \theta < 0$  if  $\pi/2 < \theta \leq \pi$ , we see that  $\mathbf{a} \cdot \mathbf{b}$  is positive for  $\theta < \pi/2$  and negative for  $\theta > \pi/2$ .
- ❖ We can think of  $\mathbf{a} \cdot \mathbf{b}$  as measuring the extent to which  $\mathbf{a}$  and  $\mathbf{b}$  point in the **same direction**.
- ❖  $\mathbf{a} \cdot \mathbf{b}$  is positive : If  $\mathbf{a}$  and  $\mathbf{b}$  point in the same general direction,
- ❖  $\mathbf{a} \cdot \mathbf{b}$  is 0: If  $\mathbf{a}$  and  $\mathbf{b}$  they are perpendicular
- ❖  $\mathbf{a} \cdot \mathbf{b}$  is negative: If  $\mathbf{a}$  and  $\mathbf{b}$  point generally opposite directions (see Figure 2).

Figure 2

# Direction Angles and Direction Cosines

# Direction Angles and Direction Cosines

- ❖ The direction angles of a nonzero vector  $\mathbf{a}$  are the angles  $\alpha$ ,  $\beta$ , and  $\gamma$  (in the interval  $[0, \pi]$ ) that  $\mathbf{a}$  makes with the **positive** x-, y-, and z-axes. (See Figure 3.)

Figure 3

# Direction Angles and Direction Cosines

❖ The cosines of these direction angles,  $\cos \alpha$ ,  $\cos \beta$ , and  $\cos \gamma$ , are called the direction cosines of the vector  $\mathbf{a}$ . Using Corollary 6 with  $\mathbf{b}$  replaced by  $\mathbf{i}$ , we obtain

$$\boxed{8} \quad \cos \alpha = \frac{\mathbf{a} \cdot \mathbf{i}}{|\mathbf{a}| |\mathbf{i}|} = \frac{a_1}{|\mathbf{a}|}$$

❖ (This can also be seen directly from Figure 3.) Similarly, we also have

$$\boxed{9} \quad \cos \beta = \frac{a_2}{|\mathbf{a}|} \quad \cos \gamma = \frac{a_3}{|\mathbf{a}|}$$

# Direction Angles and Direction Cosines

$$\cos \alpha = \frac{\mathbf{a} \cdot \mathbf{i}}{|\mathbf{a}| |\mathbf{i}|} = \frac{a_1}{|\mathbf{a}|} \quad \cos \beta = \frac{a_2}{|\mathbf{a}|} \quad \cos \gamma = \frac{a_3}{|\mathbf{a}|}$$

❖ Using the above equations we can write

$$\mathbf{a} = \langle a_1, a_2, a_3 \rangle = \langle |\mathbf{a}| \cos \alpha, |\mathbf{a}| \cos \beta, |\mathbf{a}| \cos \gamma \rangle$$

$$= |\mathbf{a}| \langle \cos \alpha, \cos \beta, \cos \gamma \rangle$$

# Direction Angles and Direction Cosines

## ❖ Example:

❖ Find the direction angles of the vector  $\mathbf{a} = \langle 1, 2, 3 \rangle$ .

❖ Solution:  $|\mathbf{a}| = \sqrt{1^2 + 2^2 + 3^2} = \sqrt{14},$

❖ Since

Equations 8 and 9 give

$$\cos \alpha = \frac{1}{\sqrt{14}} \quad \cos \beta = \frac{2}{\sqrt{14}} \quad \cos \gamma = \frac{3}{\sqrt{14}}$$

❖ and so

$$\alpha = \cos^{-1}\left(\frac{1}{\sqrt{14}}\right) \approx 74^\circ \quad \beta = \cos^{-1}\left(\frac{2}{\sqrt{14}}\right) \approx 58^\circ \quad \gamma = \cos^{-1}\left(\frac{3}{\sqrt{14}}\right) \approx 37^\circ$$

# Projections

# Projections

56

❖ Figure 4 shows representations  $\overrightarrow{PQ}$  and  $\overrightarrow{PR}$  of two vectors  $\mathbf{a}$  and  $\mathbf{b}$  with the same initial point  $P$ .

❖ Projections are of two types: **Vector and Scalar**

Vector projections

Scalar projections

Figure 4

# Scalar Projections

57

❖ **Scalar Projection:** The scalar projection of **b** onto **a** is defined to be **the component of **b** along **a****, which is the number  $|\mathbf{b}| \cos \theta$ , where  $\theta$  is the angle between **a** and **b**. (See Figure 5.)

❖ Scalar projection is denoted by  $\text{comp}_a \mathbf{b}$ .

Scalar projection

Figure 5

# Relation between Dot Product and Scalar Projection

❖ The equation  $\mathbf{a} \cdot \mathbf{b} = |\mathbf{a}| |\mathbf{b}| \cos \theta = |\mathbf{a}| (|\mathbf{b}| \cos \theta)$

❖ shows that the **dot product** of  $\mathbf{a}$  and  $\mathbf{b}$  can be interpreted as the **length of  $\mathbf{a}$  times the scalar projection of  $\mathbf{b}$  onto  $\mathbf{a}$** . Since

$$|\mathbf{b}| \cos \theta = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|} = \frac{\mathbf{a}}{|\mathbf{a}|} \cdot \mathbf{b}$$

❖ The **comp<sub>a</sub> b** can be computed by taking the dot product of  $\mathbf{b}$  with the unit vector in the direction of  $\mathbf{a}$ .

# Vector Projections

❖ **Vector Projection:** If  $S$  is the foot of the perpendicular from  $R$  to the line containing  $PQ$ , then the vector with representation  $\overrightarrow{PS}$  is called the vector projection of  $b$  onto  $a$  and is denoted by  $\text{proj}_a \mathbf{b}$ . (You can think of it as a shadow of  $b$ ).

Vector projections

Figure 4

# Vector Projections

❖ We summarize these ideas as follows.

Scalar projection of  $\mathbf{b}$  onto  $\mathbf{a}$ :  $\text{comp}_{\mathbf{a}} \mathbf{b} = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|}$

Vector projection of  $\mathbf{b}$  onto  $\mathbf{a}$ :  $\text{proj}_{\mathbf{a}} \mathbf{b} = \left( \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|} \right) \frac{\mathbf{a}}{|\mathbf{a}|} = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|^2} \mathbf{a}$

❖ Notice that the vector projection is the **scalar projection times the unit vector in the direction of  $\mathbf{a}$ .**

# Projection

❖ **Example:** Find the scalar projection and vector projection of  $\mathbf{b} = \langle 1, 1, 2 \rangle$  onto  $\mathbf{a} = \langle -2, 3, 1 \rangle$ .

❖ **Solution:**

❖ The **scalar projection** of  $\mathbf{b}$  onto  $\mathbf{a}$  is:

$$\text{comp}_{\mathbf{a}} \mathbf{b} = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|}$$

$$|\mathbf{a}| = \sqrt{(-2)^2 + 3^2 + 1^2} = \sqrt{14},$$

$$\begin{aligned} \text{comp}_{\mathbf{a}} \mathbf{b} &= \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|} = \frac{(-2)(1) + 3(1) + 1(2)}{\sqrt{14}} \\ &= \frac{3}{\sqrt{14}} \end{aligned}$$

# Example 6 – Solution

62

cont'd

❖ **Vector projection:** is this scalar projection times the unit vector in the direction of  $\mathbf{a}$ :

$$\begin{aligned}\text{proj}_{\mathbf{a}} \mathbf{b} &= \frac{3}{\sqrt{14}} \frac{\mathbf{a}}{|\mathbf{a}|} \\ &= \frac{3}{14} \mathbf{a} \\ &= \left\langle -\frac{3}{7}, \frac{9}{14}, \frac{3}{14} \right\rangle\end{aligned}$$

# The Cross Product

# The Cross Product

❖ The cross product (also known as vector product)  $\mathbf{a} \times \mathbf{b}$ , is a vector  $\mathbf{c}$  that is **perpendicular** to both  $\mathbf{a}$  and  $\mathbf{b}$ .

**8 Theorem** The vector  $\mathbf{a} \times \mathbf{b}$  is orthogonal to both  $\mathbf{a}$  and  $\mathbf{b}$ .

# The Cross Product

❖ Given two nonzero vectors  $\mathbf{a} = \langle a_1, a_2, a_3 \rangle$  and  $\mathbf{b} = \langle b_1, b_2, b_3 \rangle$ , we want to find  $\mathbf{c}$  that is perpendicular to both  $\mathbf{a}$  and  $\mathbf{b}$ ,

❖ If  $\mathbf{c} = \langle c_1, c_2, c_3 \rangle$  is such a vector, then  $\mathbf{a} \cdot \mathbf{c} = 0$  and  $\mathbf{b} \cdot \mathbf{c} = 0$  and so

❖ 
$$a_1c_1 + a_2c_2 + a_3c_3 = 0$$

❖ 
$$b_1c_1 + b_2c_2 + b_3c_3 = 0$$

# The Cross Product

**4 Definition** If  $\mathbf{a} = \langle a_1, a_2, a_3 \rangle$  and  $\mathbf{b} = \langle b_1, b_2, b_3 \rangle$ , then the **cross product** of  $\mathbf{a}$  and  $\mathbf{b}$  is the vector

$$\mathbf{a} \times \mathbf{b} = \langle a_2b_3 - a_3b_2, a_3b_1 - a_1b_3, a_1b_2 - a_2b_1 \rangle$$

- ❖ Notice that the cross product  $\mathbf{a} \times \mathbf{b}$  of two vectors  $\mathbf{a}$  and  $\mathbf{b}$ , unlike the dot product, is a vector. For this reason it is also called **the vector product**.
- ❖ Note that  $\mathbf{a} \times \mathbf{b}$  is defined only when  $\mathbf{a}$  and  $\mathbf{b}$  are **three-dimensional vectors**.

# The Cross Product using Determinant

❖ A determinant of order 2 :

$$\begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc$$

❖ For example,

$$\begin{vmatrix} 2 & 1 \\ -6 & 4 \end{vmatrix} = 2(4) - 1(-6) = 14$$

# The Cross Product using Determinant

68

Cont'd

❖ A determinant of order 3 :

$$\begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix} = a_1 \begin{vmatrix} b_2 & b_3 \\ c_2 & c_3 \end{vmatrix} - a_2 \begin{vmatrix} b_1 & b_3 \\ c_1 & c_3 \end{vmatrix} + a_3 \begin{vmatrix} b_1 & b_2 \\ c_1 & c_2 \end{vmatrix}$$

❖ The number  $a_i$  in the first row is multiplied by the second-order determinant ( obtained from the left side by deleting the row and column in which  $a_i$  appears.)

❖ Notice also the **minus sign** in the second term.

# The Cross Product

## ❖ Example:

❖ If  $\mathbf{a} = \langle 1, 3, 4 \rangle$  and  $\mathbf{b} = \langle 2, 7, -5 \rangle$ , then

$$\mathbf{a} \times \mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 3 & 4 \\ 2 & 7 & -5 \end{vmatrix}$$

$$= \begin{vmatrix} 3 & 4 \\ 7 & -5 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & 4 \\ 2 & -5 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 3 \\ 2 & 7 \end{vmatrix} \mathbf{k}$$

❖  $= (-15 - 28)\mathbf{i} - (-5 - 8)\mathbf{j} + (7 - 6)\mathbf{k}$

❖  $= -43\mathbf{i} + 13\mathbf{j} + \mathbf{k}$

# Right-hand Rule: The Cross Product

72

- ❖ If  $\mathbf{a}$  and  $\mathbf{b}$  are represented by directed line segments with the same initial point (as in Figure 1), then the cross product  $\mathbf{a} \times \mathbf{b}$  points in a direction **perpendicular** to the plane through  $\mathbf{a}$  and  $\mathbf{b}$ .

The right-hand rule gives the **direction** of  $\mathbf{a} \times \mathbf{b}$ .

Figure 1

# Right-hand Rule: The Cross Product

73

- ❖ **The right-hand rule:** If the fingers of your **right hand curl** in the direction of a rotation (through an angle less than  $180^\circ$ ) from **a** to **b**, then your **thumb points in the direction of  $\mathbf{a} \times \mathbf{b}$** .
- ❖ Now that we know the direction of the vector  $\mathbf{a} \times \mathbf{b}$ , the remaining thing we need to complete its geometric description is its **length  $|\mathbf{a} \times \mathbf{b}|$** . This is given by the following theorem.

**9 Theorem** If  $\theta$  is the angle between **a** and **b** (so  $0 \leq \theta \leq \pi$ ), then

$$|\mathbf{a} \times \mathbf{b}| = |\mathbf{a}| |\mathbf{b}| \sin \theta$$

# Properties of The Cross Product

❖ The following theorem summarizes the properties of vector products.

**11 Theorem** If  $\mathbf{a}$ ,  $\mathbf{b}$ , and  $\mathbf{c}$  are vectors and  $c$  is a scalar, then

1.  $\mathbf{a} \times \mathbf{b} = -\mathbf{b} \times \mathbf{a}$
2.  $(c\mathbf{a}) \times \mathbf{b} = c(\mathbf{a} \times \mathbf{b}) = \mathbf{a} \times (c\mathbf{b})$
3.  $\mathbf{a} \times (\mathbf{b} + \mathbf{c}) = \mathbf{a} \times \mathbf{b} + \mathbf{a} \times \mathbf{c}$
4.  $(\mathbf{a} + \mathbf{b}) \times \mathbf{c} = \mathbf{a} \times \mathbf{c} + \mathbf{b} \times \mathbf{c}$
5.  $\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c}) = (\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c}$
6.  $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = (\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}$
